## Atomic Weights of the Elements<sup>a)</sup> 1999

#### T. B. Coplen<sup>b)</sup>

U.S. Geological Survey, 431 National Center, Reston, Virginia 20192

(Received June 6 2001; revised manuscript received June 20 2001)

The biennial review of atomic-weight,  $A_r(E)$ , determinations and other cognate data have resulted in changes for the standard atomic weights of the following elements:

	from	to
nitrogen	$14.00674\pm0.00007$	$14.0067 \pm 0.0002$
sulfur	$32.066 \pm 0.006$	$32.065 \pm 0.005$
chlorine	$35.4527 \pm 0.0009$	$35.453 \pm 0.002$
germanium	$72.61\pm0.02$	$72.64 \pm 0.01$
xenon	$131.29 \pm 0.02$	$131.293 \pm 0.006$
erbium	$167.26 \pm 0.03$	$167.259 \pm 0.003$
uranium	$238.0289 \pm 0.0001$	$238.02891\pm0.00003$

Presented are updated tables of the standard atomic weights and their uncertainties estimated by combining experimental uncertainties and terrestrial variabilities. In addition, this report again contains an updated table of relative atomic mass values and half-lives of selected radioisotopes. Changes in the evaluated isotopic abundance values from those published in 1997 are so minor that an updated list will not be published for the year 1999. Many elements have a different isotopic composition in some nonterrestrial materials. Some recent data on parent nuclides that might affect isotopic abundances or atomic-weight values are included in this report for the information of the interested scientific community. © 2001 American Institute of Physics.

Key words: atomic weight; critcal evaluation; elements; isotopic composition.

#### 1. Introduction

The Commission on Atomic Weights and Isotopic Abundances met under the chairmanship of Professor L. Schultz from 8th–10th August 1999 during the 40th IUPAC General Assembly in Berlin, Germany. The Commission decided to

a) International Union of Pure and Applied Chemistry, Inorganic Chemistry Division, Commission on Atomic Weights and Isotopic Abundances, Membership of the Commission for the period 1998–1999 was as follows:

L. Schultz (Germany, Chairman); R. D. Vocke, Jr. (USA, Secretary); J. K. Böhlke (USA, Titular); T. Ding (China, Associate); M. Ebihara (Japan, Titular); A. N. Halliday (USA, Associate); H.-J. Kluge (Germany, Associate); R. D. Loss (Australia, Titular); G. Ramendik (Russia, Titular); D. J. Rokop (USA, Associate); M. Stiévenard (France, Associate); P. D. P. Taylor (Belgium, Titular); S. Yoneda (Japan, Associate); P. De Bièvre (Belgium, National Representative); J. R. de Laeter (Australia, National Representative); Y. Do (Korea, National Representative); N. N. Greenwood (UK, National Representative); M. Shima (Japan, National Representative); Y. K. Xiao (China, National Representative). Reprinted with permission of the International Union of Pure and Applied Chemistry from Pure Appl. Chem. 73, 667–683 (2001).

publish the report "Atomic Weights of the Elements 1999" as presented here. The resulting current Table of Standard Atomic Weights is given in alphabetical order of the principal English names in Table 1 and in order of atomic number in Table 2. The atomic weights reported in Tables 1 and 2 are for atoms in their electronic and nuclear ground states.

The Commission reviewed the literature over the previous two years since the last report on atomic weights and evaluated the published data on atomic weights and isotopic compositions on an element-by-element basis. The atomic weight,  $A_r(E)$ , of element E can be determined from a knowledge of the isotopic abundances and corresponding atomic masses of the nuclides of that element. Compilations of the abundances of the isotopes were published in  $1998^2$  and the atomic-mass evaluations of  $1993^3$  have been used by the Commission. The Commission periodically reviews the history of the atomic weight of each element emphasizing the relevant published scientific evidence on which decisions have been made.<sup>4</sup>

The Commission wishes to emphasize the need for new precise calibrated isotopic composition measurements in order to improve the accuracy of the atomic weights of a number of elements, which are still not known to a satisfactory level of accuracy. For many elements the limited accuracy of measurements, however, is overshadowed by terrestrial variability, which is combined in the tabulated uncertainty of the atomic weights.

For all elements for which a change in the  $A_r(E)$  value or its uncertainty,  $U[A_r(E)]$  (in parentheses, following the last significant figure to which it is attributed), is recommended, the Commission by custom makes a statement on the reason for the change and includes a list of past recommended values over a period in excess of the last 100 years, which are taken from Coplen and Peiser, 1998. Values before the formation of the International Committee on Atomic Weights in 1900 come from Clarke.

The names and symbols for those elements with atomic numbers 110–118 referred to in the following tables are systematic and based on the atomic numbers of the elements recommended for provisional use by the IUPAC Commission on the Nomenclature of Inorganic Chemistry. These systematic names and symbols will be replaced by a permanent name approved by IUPAC, once the priority of discovery is established and the name suggested by the discoverers is examined and reviewed. The name is derived directly from the atomic number of the element using the following numerical roots:

1 un	2 bi	3 tri	4 quad	5 pent
6 hex	7 sept	8 oct	9 enn	0 nil

The roots are put together in the order of the digits that make up the atomic number and terminated by "ium" to spell out the name. The final "n" of "enn" is deleted when it occurs before "nil," and the final "i" of "bi" and of "tri" is deleted when it occurs before "ium."

# 2. Comments on Some Atomic Weights and Annotations

#### 2.1. Nitrogen

The Commission has changed the recommended value for the standard atomic weight of nitrogen to  $A_r(N)$ = 14.0067(2) based on an evaluation of the variation in isotopic abundance of naturally occurring nitrogen-bearing substances. The Commission decided that the uncertainty of  $A_r(N)$  should be increased so that the implied range in relation to terrestrial variability is similar to that of other elements with significant natural isotopic variation, such as hydrogen, oxygen, and carbon. However, footnote "g" remains in Tables 1 and 2 to warn users that highly unusual naturally occurring nitrogen-bearing substances can be found with an atomic weight that falls outside the implied range. The previous value,  $A_r(N) = 14.00674(7)$ , was adopted by the Commission in 1985<sup>4</sup> and was based on a change in the procedures for reporting uncertainties, taking into account mass spectrometric measurements of nitrogen in air by Junk and Svec in 1958. Historical values of  $A_r(N)$  include: 1882, 14.03; 1895, 14.05; 1896, 14.04; 1907, 14.01; 1919, 14.008; 1961, 14.0067(3); and 1969, 14.0067(1).

#### 2.2. Sulfur

The Commission has changed the recommended value for the standard atomic weight of sulfur to  $A_r(S) = 32.065(5)$ based on a redetermination of the atomic weight of the Canon Diablo troilite (CDT) reference material (32.064) and a re-evaluation of the variation in sulfur isotopic abundances of naturally occurring S-bearing substances. The new standard atomic weight and its uncertainty include almost all known values in terrestrial materials; however, the footnote "g" remains to alert users to the existence of rare materials with atomic weights outside that range. Sulfur has a bimodal natural atomic-weight distribution so that in practice one is more likely to find materials with either lower or higher atomic-weight values than 32.065. New calibrated mass spectrometric measurements of the isotopic composition of the IAEA-S-1 silver sulfide reference material<sup>9,10</sup> indicate that the atomic weight of CDT is 32.064, which is in agreement with the atomic weight of meteoritic sulfur determined by McNamara and Thode. 11 The previous standard atomic weight value,  $A_r(S) = 32.066(6)$ , was adopted by the Commission in 1983 based on a compilation of isotopic variations of naturally occurring materials. Historical values of  $A_r(S)$ include: 1882, 32.06; 1896, 32.07; 1903, 32.06; 1909, 32.07; 1916, 32.06; 1925, 32.064; 1931, 32.06; 1947, 32.056; 1961, 32.064(3); and 1969, 32.06(1).

#### 2.3. Chlorine

The Commission has changed the recommended value for the standard atomic weight of chlorine to  $A_r(Cl)$ = 35.453(2), based on an evaluation of the variation in isotopic abundances of naturally occurring chlorine-bearing

TABLE 1. Standard atomic weights 1999. Alphabetical order in English. [Scaled to  $A_r(^{12}\mathrm{C}) = 12$ , where  $^{12}\mathrm{C}$  is a neutral atom in its nuclear and electronic ground state.] The atomic weights of many elements are not invariant but depend on the origin and treatment of the material. The standard values of  $A_r(\mathrm{E})$  and the uncertainties (in parentheses, following the last significant figure to which they are attributed) apply to elements of natural terrestrial origin. The footnotes to this table elaborate the types of variation which may occur for individual elements and which may be larger than the listed uncertainties of values of  $A_r(\mathrm{E})$ . Names of elements with atomic number 110–118 are provisional

TABLE 1. Standard atomic weights 1999. Alphabetical order in English. [Scaled to  $A_r(^{12}\text{C}) = 12$ , where  $^{12}\text{C}$  is a neutral atom in its nuclear and electronic ground state.] The atomic weights of many elements are not invariant but depend on the origin and treatment of the material. The standard values of  $A_r(E)$  and the uncertainties (in parentheses, following the last significant figure to which they are attributed) apply to elements of natural terrestrial origin. The footnotes to this table elaborate the types of variation which may occur for individual elements and which may be larger than the listed uncertainties of values of  $A_r(E)$ . Names of elements with atomic number 110–118 are provisional—Continued

Name	Symbol	Atomic number	Atomic weight	Footnotes <sup>c</sup>
Xenon	Xe	54	131.293(6)	g m
Ytterbium	Yb	70	173.04(3)	g
Yttrium	Y	39	88.90585(2)	
Zinc	Zn	30	65.39(2)	
Zirconium	Zr	40	91.224(2)	g

<sup>&</sup>lt;sup>a</sup>Element has no stable nuclides. One or more well-known isotopes are given in Table 3 with the appropriate relative atomic mass and half-life. However, three such elements (Th, Pa, and U) do have a characteristic terrestrial isotopic composition, and for these an atomic weight is tabulated.

substances. The Commission decided that the uncertainty of  $A_r(Cl)$  should be increased so that the implied range in relation to terrestrial variability is similar to that of other elements with significant natural isotopic variation, such as hydrogen, oxygen, and carbon. To reflect the fact that the new atomic weight of Cl and its uncertainty were assigned on the basis of known variability, the footnote "r" was added to Tables 1 and 2. The footnote "g" has been added to Tables 1 and 2 to alert users that highly unusual naturally occurring chlorine-bearing substances can be found with an atomic weight that falls outside the implied range. The previous value,  $A_r(Cl) = 35.4527(9)$ , was adopted by the Commission in 19854 and was based on a change in the procedures for reporting uncertainties, taking into account the calibrated mass spectrometric measurements of chlorine by Shields et al. 12 Historical values of  $A_r(Cl)$  include: 5 1882, 35.45; 1909, 35.46; 1925, 35.457; 1961, 35.453; and 1969, 35.453(1).

#### 2.4. Germanium

The Commission has changed the recommended value for the standard atomic weight of germanium to  $A_r(Ge) = 72.64(1)$ , based on calibrated mass spectrometric measurements by Chang *et al.*<sup>13</sup> Measurements were carried out on five germanium samples of high purity (Ge metal and  $GeO_2$ ) from America, Europe, and Asia using positive thermal ionization mass spectrometry. The previous value of  $A_r(Ge) = 72.61(2)$  was assigned by the Commission in 1985,<sup>4</sup> which considered the discrepancy between atomic weights determined by mass spectrometry and chemical methods.<sup>4,14</sup> By recent high quality mass spectrometric mea-

surements, the mass spectrometric data are confirmed. Historical values of  $A_r$ (Ge) include: <sup>5</sup> 1894, 72.3; 1897, 72.48; 1900, 72.5; 1925, 72.60; 1961, 72.59; and 1969, 72.59(3).

#### 2.5. Xenon

The Commission has changed the recommended value for the standard atomic weight of xenon to  $A_r(Xe) = 131.293(6)$ , based on a new calibrated mass spectrometric measurement of Valkiers *et al.*<sup>15</sup> on a tank of purified xenon. The footnote "g" in Tables 1 and 2 arises from the presence of naturally occurring fission products found at fossil reactors at The Gabon, Africa. The previous value,  $A_r(Xe) = 131.29(2)$ , was adopted by the Commission in 1985<sup>4</sup> and was based on a change in the procedures for reporting uncertainties, and it took into account the mass spectrometric measurements of Nier. Historical values of  $A_r(Xe)$  include: 1902, 128; 1910, 130.7; 1911, 130.2; 1932, 131.3; 1955, 131.30; 1969, 131.30(1); and 1979, 131.29(3).

#### 2.6. Erbium

The Commission has changed the recommended value for the standard atomic weight of erbium to  $A_r(Er) = 167.259(3)$ , based on calibrated measurements with highly enriched erbium isotopes using positive thermal ionization mass spectrometry and a multicollector system. <sup>17</sup> The value for the uncertainty takes into account the lack of adequate quantification of collector calibration. Erbium isolated from a kaolinite mineral and from four different commercially available Er-bearing materials did not show any isotope variation. Nevertheless, footnote "g" in Tables 1 and 2

<sup>&</sup>lt;sup>b</sup>Commercially available Li materials have atomic weights that range between 6.939 and 6.996; if a more accurate value is required, it must be determined for the specific material.

<sup>&</sup>lt;sup>c</sup>(g) Geological specimens are known in which the element has an isotopic composition outside the limits for normal material. The difference between the atomic weight of the element in such specimens and that given in the table may exceed the stated uncertainty.

<sup>(</sup>m) Modified isotopic compositions may be found in commercially available material because it has been subjected to an undisclosed or inadvertent isotopic fractionation. Substantial deviations in atomic weight of the element from that given in the table can occur.

<sup>(</sup>r) Range in isotopic composition of normal terrestrial material prevents a more precise  $A_r(E)$  being given; the tabulated  $A_r(E)$  value should be applicable to any normal material.

TABLE 2. Standard atomic weights 1999. Order of atomic number. [Scaled to  $A_r(^{12}\mathrm{C}) = 12$ , where  $^{12}\mathrm{C}$  is a neutral atom in its nuclear and electronic ground state.] The atomic weights of many elements are not invariant but depend on the origin and treatment of the material. The standard values of  $A_r(E)$  and the uncertainties (in parentheses, following the last significant figure to which they are attributed) apply to elements of natural terrestrial origin. The footnotes to this table elaborate the types of variation which may occur for individual elements and which may be larger than the listed uncertainties of values of  $A_r(E)$ . <sup>&</sup>lt;sup>a</sup>Element has no stable nuclides. One or more well-known isotopes are given in Table 3 with the appropriate relative atomic mass and half-life. However, three such elements (Th, Pa, and U) do have a characteristic terrestrial isotopic composition, and for these an atomic weight is tabulated.

arises from the presence of naturally occurring fission products found at fossil reactors at The Gabon, Africa. The previous value,  $A_r(\text{Er}) = 167.26(3)$ , was adopted by the Commission in 1961, based on isotopic abundance measurements of erbium by Hayden *et al.*<sup>18</sup> and Leland<sup>19</sup> and atomic masses of Bhanot *et al.*<sup>20</sup> Historical values of  $A_r(\text{Er})$  include: 1882, 166.27; 1894, 166.3; 1897, 166.32; 1900, 166.0; 1909, 167.4; 1912, 167.7; 1931, 167.64; 1934, 165.20; 1935, 167.84; 1938, 167.2; 1955, 167.22; 1961, 167.26; 1969, 167.26(3).

#### 2.7. Uranium

The Commission has changed the recommended value for the standard atomic weight of uranium to  $A_r(U)$ = 238.02891(3) based on the calibrated mass spectrometric determinations by Richter et al.21 These measurements reflect the improved capability of current double focusing mass spectrometers with pulse counting ion-detection systems for determination of low abundance isotopes and updated gas mass spectrometry measurements of the major isotopes. All measurements were based on internal normalization against well characterized isotope standards. A set of six ore samples collected worldwide was utilized for the measurements. That value applies to uranium as found in normal terrestrial sources, except as discovered in one locality in Africa (The Gabon at Oklo), hence the footnote "g" in Tables 1 and 2. The previous value,  $A_r(U) = 238.0289(1)$ , was adopted by the Commission in 1979 taking into account the studies on isotopic variation by Cowan and Adler<sup>22</sup> and Smith and Jackson,<sup>23</sup> and mass spectrometric measurements of White et al.<sup>24</sup> and Greene et al.<sup>25</sup> Historical values of  $A_r(U)$ include:5 1882, 239.03; 1894, 239.6; 1896, 239.59; 1900, 239.6; 1903, 238.5; 1916, 238.2; 1925, 238.17; 1931, 238.14; 1937, 238.07; 1961, 238.03; and 1969, 238.029(1).

# 3. Relative Atomic Mass Values and Half-Lives of Selected Radionuclides

For elements that have no stable or long-lived nuclides, the data on radioactive half-lives and relative atomic mass values for the nuclides of interest and importance have been evaluated, and the recommended values and uncertainties are listed in Table 3.

As has been the custom in the past, the Commission publishes a table of relative atomic mass values and half-lives of selected radionuclides. The Commission has no prime responsibility for the dissemination of such values. There is no general agreement on which of the nuclides of the radioactive elements is, or is likely to be judged, "important." Various criteria such as "longest half-life," "production in quantity," and "used commercially," have been applied in the past to the Commission's choice.

The information contained in this table will enable the user to calculate the atomic weight for radioactive materials with a variety of isotopic compositions. Atomic-mass values have been taken from the 1997 Atomic Mass Table.<sup>3</sup> Some of these half-lives have already been documented.<sup>26–29</sup>

#### 4. Nonterrestrial Data

The isotopic abundance of elements in many nonterrestrial samples within the solar system can be measured directly by analysis of meteorites and other interplanetary materials. In recent years, the increasing sophistication of analytical in-

<sup>&</sup>lt;sup>b</sup>Commercially available Li materials have atomic weights that range between 6.939 and 6.996; if a more accurate value is required, it must be determined for the specific material.

<sup>&</sup>lt;sup>c</sup>(g) Geological specimens are known in which the element has an isotopic composition outside the limits for normal material. The difference between the atomic weight of the element in such specimens and that given in the table may exceed the stated uncertainty.

<sup>(</sup>m) Modified isotopic compositions may be found in commercially available material because it has been subjected to an undisclosed or inadvertent isotopic fractionation. Substantial deviations in atomic weight of the element from that given in the table can occur.

<sup>(</sup>r) Range in isotopic composition of normal terrestrial material prevents a more precise  $A_r(E)$  being given; the tabulated  $A_r(E)$  value should be applicable to any normal material.

Table 3. Relative atomic masses and half-lives of selected radionuclides. (Prepared, as in previous years, by N. E. Holden, a former Commission member; a=year; d=day; h=hour; min=minute; s=second. Names of elements with atomic number 110–118 are provisional.)

<sup>&</sup>lt;sup>a</sup>The uncertainties of these elements are unsymmetric.

strumentation and techniques have enabled the isotopic composition of submicron sized components in nonterrestrial samples to be determined. At the same time there has also been an increase in the use of on-board spacecraft and ground-based astronomical spectrometers to measure isotopic abundances remotely. These advances have substantially increased the number of isotopic composition data for nonterrestrial materials.

The extensive analysis of nonterrestrial materials has continued to show that many elements in nonterrestrial materials have different isotopic compositions from those in terrestrial samples. Although most of the reported differences in the isotopic compositions in nonterrestrial materials are small compared with corresponding differences in normal terrestrial materials, some variations are quite large. For this reason, scientists who deal with the chemical analysis of nonterrestrial samples should exercise caution when the isotopic composition or the atomic weight of nonterrestrial samples is needed. Most isotropic variations observed in nonterrestrial materials are currently explained by the following processes:

- (i) Mass fractionation. Mass dependent isotopic fractionation can also be observed in many terrestrial materials, but the magnitude of mass dependent isotopic fractionation in nonterrestrial samples is generally larger than that found in terrestrial samples. Mass dependent isotopic fractionation observed in nonterrestrial samples is mostly due to volatilization or condensation, which most likely occurred at the early stage of the formation of the solar system. Mass dependent isotopic fractionation may also have occurred at later stages in the evolution of the solar system by chemical processes such as the formation of organic compounds.
- (ii) Nuclear reaction. Nuclear reactions triggered by cosmic rays can alter the isotopic composition of not only nonterrestrial but also terrestrial materials. This effect in terrestrial samples is normally negligible, mainly because of effective shielding against cosmic rays by the Earth's magnetosphere and atmosphere. In contrast, nonterrestrial materials are often exposed to sufficient solar and galactic cosmic ray fluxes to cause significant nuclear spallation reactions, which in turn trigger secondary low energy neutron capture reactions at specific depths from the surface or near the surface of samples.

(iii) Radioactive decay. Isotopic anomalies due to radioactive decay are not limited to nonterrestrial samples. Nevertheless, their effect can be clearly observed in nonterrestrial samples both in the degree of the alteration of isotopic abundances and in the variety of radioactive nuclides. Enrichment in decay products is the most common effect confirmed in the nonterrestrial samples. The effect is caused by long-lived nuclides (primary radioactive nuclides), whose half-lives are

Fig. 1. Mass spectrum of Xe extracted from the Richardton meteorite (Reynolds<sup>31</sup>). Horizontal lines indicate the comparison spectrum of terrestrial Xe normalized to  $^{132}$ Xe. A large excess at  $^{129}$ Xe is due to radioactive decay of a parent nuclide,  $^{129}$ I (half-life= $1.6 \times 10^7$  a).

<sup>&</sup>lt;sup>b</sup>The value given is determined from only a few decays.

Parent nuclide	Half-life in 10 <sup>6</sup> a	Decay mode	Daughter nuclide	Absolute difference between the observed isotopic ratio and that found in normal terrestrial materials	Refs.
<sup>26</sup> Al	0.72	$\beta^+$ , EC	<sup>26</sup> Mg	0.095 ( <sup>26</sup> Mg/ <sup>24</sup> Mg)	32

TABLE 4. Examples of measurements of anomalous isotopic compositions in extraterrestrial materials arising from the earlier decay of radioisotopes

comparable to the age of our solar system  $(4.56 \times 10^9 \text{ a})$ . These nuclides are commonly used in geochronology and cosmochronology.

The next observed effect caused by radioactive decay is due to parent nuclides that have decayed. While such nuclides are no longer present in the solar system, their former presence in nonterrestrial materials can be demonstrated by excesses in decay products, which together with their parent(s) have been part of a closed isotopic system. Their measurement provides valuable information related to the time from their final nucleosynthetic contribution to the solar system to their incorporation to solar system materials (also known as the solar system formation interval).

In addition to these two major effects, some minor effects can be observed in nonterrestrial samples such as those caused by double  $\beta$  decay of long-lived radionuclides and nuclear fission (spontaneous and neutron-induced).

(iv) Nucleosynthesis. The most significant isotopic alteration effect observed in nonterrestrial materials (mainly meteorites) is due to nucleosynthesis. Prior to the availability of secondary ion mass spectrometry (SIMS), the majority of isotopic effects due to nucleosynthesis were known to be present in only a few component samples present in a limited number of rare meteorites. The majority of these isotopic abundance variations were best ascribed to explosive nucleosynthesis effects. Some light elements, such as oxygen and noble gas elements, showed ubiquitous isotopic anomalies (which were also considered to be related to nucleosynthetic effects) in virtually all kinds of meteoritic materials. The extensive application of the SIMS technique now shows that a large number of extra-solar materials appear to contain significant isotope anomalies. This indicates that several extra-solar materials appear to have survived the formation of the solar system either within meteorites or their components. Some of these components demonstrate huge isotopic variations, which are believed to be due to a wide range of nucleosynthetic effects occurring at various stages of stellar evolution. A number of examples have been listed in the previous Pure and Applied Chemistry publications.<sup>30</sup>

Figure 1 shows an example of how the radioactive decay of a parent nuclide, <sup>129</sup>I in this case, alters the isotopic composition of nonterrestrial materials. 129I is a typical parent nuclide and decays to  $^{129}$ Xe with a half-life of  $1.6 \times 10^7$  a. The presence of <sup>129</sup>I at the early solar system was first confirmed in 1960 by Reynolds, who observed an excess of <sup>129</sup>Xe in noble gas extracted from the Richardton meteorite. <sup>31</sup> Since then, more than ten long-living radionuclides with half-lives less than the age of the Earth have been proposed to alter the isotopic abundance of their daughter nuclide after their decay (Table 4). The isotopic composition of Xe tends to suffer other alteration processes, such as nuclear reactions (cosmic-ray produced spallation reaction and nuclear fission reaction) and mass dependent isotopic fractionation. Meteoritic Xe thus occasionally shows a highly complex isotopic composition.

The Commission does not attempt to systematically review the literature on the isotopic compositions of nonterrestrial materials in this report. Those who are interested in more comprehensive reviews, including specific data and additional references, should refer to Shima, <sup>43</sup> and Shima and Ebihara. <sup>44</sup> A more detailed report of isotopic measurement published in this field during the last decade is in preparation.

### 5. Other Projects of the Commission

At intervals of about 6–8 years, the Commission's *Sub-committee for Isotopic Abundance Measurements* publishes a summary of its biennial review of isotopic compositions of the elements as determined by mass spectrometry and other relevant methods. The subcommittee distributed their summary report at Berlin, titled "Isotopic compositions of the elements 1997." <sup>2</sup> The very few and minor 1999 changes of the evaluated best values for some isotopic abundances do

not justify the publication of an updated table which, however, is always currently maintained by and available on request from the Commission.

The rules that the Commission employs in assigning atomic-weight values are found in the Commission's *Technical Booklet*. J. de Laeter incorporated decisions made at the previous General Assembly at Geneva to produce the *Fifth Edition* of the Commission's *Technical Booklet*, which he distributed. A new addition to this booklet is a paper on the reliability of the Avogadro constant, the factor that relates measurements expressed in two SI base units (mass and amount of substance) by De Bièvre and Peiser. 45

The Subcommittee for Natural Isotopic Fractionation presented a report that was discussed and modified during the Subcommittee's meeting in Berlin, Germany, prior to the IU-PAC General Assembly in Berlin. The Subcommittee will submit a report to Pure & Applied Chemistry, consisting primarily of plots (where possible) that show the variation in natural isotopic abundance and atomic weight for the elements H, Li, B, C, N, O, Si, S, Cl, Fe, Cu, Se, Pd, and Te. A companion report that is expected to be longer will include numerous references and will be published as U.S. Geological Survey Open-File Report.

de Laeter reported on plans and progress of the Commission-approved update to the 1984 Element By Element Review. Publication of this important document is planned before the next IUPAC General Assembly in 2001 in Brisbane.

Recognizing that many of the terms the Commission uses are missing from the second edition of IUPAC's book on nomenclature (the Gold Book, McNaught and Wilkinson<sup>46</sup>), the Commission asked G. Ramendik to prepare a list of such terms and obtain review for submission to IUPAC nomenclature commissions and inclusion in the third edition of the Gold Book.

Note added in proof. The author has been informed that Lawrence Berkeley Laboratory has published a retraction of the data pertaining to element 188. Refer to the article in Science 292, 777–778 (2001) which is the August 3, 2001 issue. The author is advised that the Commission on Atomic Weights and Isotopic Abundances will remove element 118 from Tables 1 and 2 in the 2001 report on the atomic weights of the elements.
